SUBSCRIBER UNIT FOR SUPPORTING  
COMMUNICATION RATE MODIFICATIONS

[0002]

Cross Reference to Related Applications

[0003]

This application is a continuation of Application No. 09/354,042, filed July 15, 1999, which is a continuation of Application No. 08/671,067, filed June 27, 1996 now U.S. Patent No. 5,953,346, issued September 14, 1999 which application(s) are incorporated herein by reference.

[0004]

BACKGROUND

[0005]

Field of the Invention

[0006]

This invention generally relates to wireless communication systems. More particularly, the invention relates to a wireless digital CDMA communication system that selectively adjusts the data transmission rate depending upon the bandwidth required by the communication without the loss of data during the transmission rate adjustment.

[0007]

Description of Related Art

[0008]

The telecommunications industry has recently experienced strong growth in the use of wireless technology including cellular, satellite and microwave communications. As the popularity and use of wireless communication systems has increased, the finite bandwidth allocated to each type of wireless communication has become increasingly valuable. Since it is unlikely that additional bandwidth to support user growth will be allocated for existing applications, many of the recent advances in telecommunication hardware and software have been directed toward increasing the transmission rate of data while utilizing the same or a decreased bandwidth.

[0009] One of the problems associated with wireless communication of data is that many different types of communicating nodes are currently in use including computers, facsimile machines, automatic calling and answering equipment and other types of data networks. These nodes may be able to communicate at a plurality of different data rates and must be properly synchronized to avoid losing data during the establishment or maintenance of a communication.

[0010] The establishment and synchronization of communications is currently performed using a variety of different techniques. For example, the system disclosed in U.S. Patent No. 4,384,307 (Kuzmik et al.) includes a communication adapter for interfacing a transceiver to a communication line. The system requires bit level manipulation of data to properly synchronize two communicating nodes. Reformatting of data using this technique is computationally expensive and prone to errors.

[0011] Another type of system is disclosed in U.S. Patent No. 4,583,124 (Tsuji et al.) which permits two nodes to quickly establish synchronization at a desired communication speed by storing information concerning each communicating node in memory. However, requiring an originating node to store information about each receiving node is impractical given today's communication environment.

[0012] Accordingly, there is a need for a simple and effective technique for switching the data transmission rate of a communication network to the required rate while preserving the integrity of the data transmitted between two communicating nodes.

[0013] SUMMARY

[0014] The present invention is a CDMA communication system which prevents the transmission of data between communicating nodes until the data communication rate required by the communicating nodes has been completely established throughout the system. The system selectively suppresses the confirmation tone that a receiving node sends to an originating node. Accordingly, the transmission of voice, facsimile or modem data is

prevented until the communication path has been established at the desired communication rate. This permits the system to reliably transport encoded data at a plurality of data rates across a telecommunication system which may lack precise synchronization.

[0015] Accordingly, it is an object of the present invention to provide a system and method for reliably transmitting encoded data by preventing communication of data until the communication system has achieved the data transmission rate required by communicating nodes.

[0016] Other objects and advantages of the present invention will become apparent after reading the description of a presently preferred embodiment.

[0017] BRIEF DESCRIPTION OF THE DRAWING(S)

[0022] Figure 5 is a block diagram of a base station in accordance with the teachings of the present invention.

[0023] DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT(S)

[0024] The preferred embodiment will be described with reference to the drawing figures where identical numerals represent similar elements throughout.

[0025] A communication network 10 embodying the present invention is shown in Figure 1. The communication network 10 generally comprises one or more base stations 14,

each of which is in wireless communication with a plurality of subscriber units 16, which may be fixed or mobile. Each subscriber unit 16 communicates with either the closest base station 14 or the base station 14 which provides the strongest communication signal. The base stations 14 also communicate with a base station controller 20 which coordinates communications among the base stations 14. The communication network 10 may also be connected to a public switched telephone network (PSTN) 22, wherein the base station controller 20 also coordinates communications between the base stations 14 and the PSTN 22. Preferably, each base station 14 communicates with the base station controller 20 over a wireless link. Although the link between the base stations 14 and the base station controller 20 is shown as a wireless link, it should be apparent to those skilled in the art that a land line between the base stations 14 and the base station controller 20 may be provided. This is particularly applicable when a base station 14 is in close proximity to the base station controller 20.

[0026] The base station controller 20 performs several functions. Primarily, the base station controller 20 provides all of the overhead, administrative and maintenance (OA&M) signaling associated with establishing and maintaining all of wireless communications between the subscriber units 16, the base stations 14, and the base station controller 20. The base station controller 20 also provides an interface between the wireless communication system 10 and the PSTN 22. This interface includes multiplexing and demultiplexing of a plurality of communication signals that enter and leave the system 10 via the base station controller 20. Although the wireless communication system 10 is shown employing antennas to transmit RF signals, one skilled in the art will recognize that communications may be accomplished by microwave satellite uplinks.

[0027] Referring to Figure 2, the communication system 10 is generally connected to originating nodes 40 and terminating nodes 44. In order to conserve as much bandwidth as possible, the communication system 10 selectively allots the bandwidth required for supporting the data transmission rate required by the originating and terminating nodes 40,

44. In this manner, the system 10 ensures that the bandwidth is utilized efficiently. Voiced communications may be effectively transmitted across a 32 Kb/s adaptive pulse code modulation (ADPCM) channel. However, a high speed fax or data modem signal requires at least a 64 Kb/s pulse code modulation (PCM) signal to reliably transmit the communication. Many other types of modulation techniques and data transmission rates may also be utilized by originating and terminating nodes 40, 44. The system 10 must be able to effectively allocate bandwidth and dynamically switch between these data communication rates and modulation schemes on demand.

[0028] The communication system 10 provides a communication link between the originating and terminating nodes 40, 44. The originating and terminating nodes 40, 44 may comprise computers, facsimile machines, automatic calling and answering equipment, data networks or any combination of this equipment. For robust communication of data it is imperative to ensure that the communication system 10 switches to the data transmission rate required by the communicating nodes 40, 44 prior to the transmission of any data.

[0029] Referring to Figure 3, the typical procedure for establishing communications between originating nodes 40 and terminating nodes 44 is shown. The originating node 40 periodically transmits a calling tone (step 100) which indicates that a data communication, (not a voice communication), is to be transmitted. The calling tone which is sent from the originating node 40 to the terminating node 44 is detected by the terminating node 44 (step 102) which initiates several actions. First, the terminating node 44 prepares to send a data communication (step 104). Next, the terminating node 44 transmits an answering tone (step 106) to the originating node 40 to confirm that the terminating node 44 has received the calling tone. Upon receipt of the answering tone (step 108), the originating node 40 begins the transmission of data (step 110), which is received by the terminating node 44 (step 112). With the communication link established at the data transmission rate, the originating and terminating 40, 44 nodes transmit and receive data until termination of the communication.

[0030] One problem with this process is that the transmission rate of the communication system 10 is transparent to both the originating and terminating nodes 40, 44. Modification of the transmission rate from a low rate (that supports voice communication) to a high rate (that supports encoded data communication) ensures that data will be reliably and quickly transmitted over a communication channel. However, the new transmission rate must be completely established throughout the communication system 10 to prevent false interpretation of tones transmitted by the originating node 40. The originating node 40 may begin transmission of data at a high rate before the system 10 has fully switched from 32 Kb/s ADPCM to 64 Kb/s PCM resulting in loss of data.

[0031] In order to obviate tone misinterpretation and to prevent the resulting erroneous operation of the originating or terminating nodes 40, 44, the present invention blocks the transmission of the confirming tone to the originating node 40 until the new data transmission rate has been completely established throughout the communication system 10. This prevents the reception of the answering tone at the originating node 40 and ensures the reliable transportation of encoded data at a higher rate across a communication system 10 which lacks the precise synchronization which would otherwise be required.

[0032] The operation of the system 10 of the present invention will be explained with reference to Figure 4. The communication system 10 facilitates communications between an originating node 40 and a terminating node 44. As shown, the actions of the originating node 40 (steps 202, 212 and 214) and the actions of the terminating node 44 (steps 206, 207, 208 and 218) are the same as in Figure 3. The operation of the communication system 10 is transparent to both the originating node 40 and the terminating node 44.

[0033] In operation, the originating node 40 periodically transmits a calling tone (step 202) which indicates a data communication. The communication system 10 performs several actions in response to receipt of the calling tone (step 204). First, the calling tone is received at 32 Kb/s ADPCM which is the standard communication setting for voice communications. The system 10 detects the calling tone and initiates a switch to 64 Kb/s

PCM in order to handle the high-speed data transmission. This switch must be implemented by the base station 14, the subscriber unit 16 and the base station controller 20. Although the system 10 immediately begins the switching over to the new data transmission rate, the process takes approximately 1500 msec to implement. Accordingly, the system 10 transmits the calling tone to the terminating node 44 at 32 Kb/s ADPCM.

[0034] The terminating node 44 detects the calling tone (step 206) and prepares to send a data communication (step 207). The terminating node 44 subsequently transmits the answering tone (step 208) which, when received by the originating node, will cause the originating node 40 to begin transmission of data.

[0035] The communication system 10 receives the answering tone from the terminating node 44. However, the system 10 does not forward the answering tone to the originating node 40 until the switch to 64 Kb/s PCM has been established throughout the system 10. After the system 10 has confirmed that the switch to 64 Kb/s PCM has been achieved, it permits the answering tone to pass through to the originating node 40, which receives the tone (step 212). In response to the answering tone, the originating node 40 begins transmission of data (step 214). The system 10 receives the data and begins transmission of data at the new data transmission rate (64 Kb/s PCM) (step 216) to the terminating node 44 which receives the data (step 218). Since the communication channel has been established, the originating and terminating nodes 40, 44 continue to communicate over the system 10 in this manner (steps 214, 216 and 218) until the communication is terminated.

[0036] Referring to Figure 5, a more detailed block diagram of the base station controller 20 is shown. The base station controller 20 controls at least a portion of the communication link between two communicating nodes 40, 44. This link comprises the transmission path 300 from a first communicating node to the base station controller 20, the transmission path 302 within the base station controller 20, and the transmission path 304 from the base station controller 20 to the second communicating node. The transmission

paths 300, 304 to and from the base station controller 20 may include a plurality of base stations 14 and subscriber units 16 which are controlled by the base station controller 20.

[0037] It should be appreciated by those of skill in the art that the establishment of a communication channel between communicating nodes 40, 44 is a complex procedure involving a plurality of tasks performed by the base station 14, the subscriber unit 16 and the base station controller 20. A detailed description of the entire procedure is outside the scope of the present invention. Accordingly, only those portions of the procedure for establishment of a communication channel relevant to the present invention will be described hereinafter.

[0038] The communications between an originating node 40 and a terminating node 44 are transmitted over a virtual channel as is well known by those of skill in the art. Since the entire spectrum is used by the CDMA communication system 10, communications from the originating node 40 to the terminating node 44 are transmitted over the same frequency band as communications from the terminating node 44 to the originating node 40. After the virtual channel has been established, the originating and terminating nodes 40, 44 may freely communicate.

[0039] The base station controller 20 includes a calling tone detector 310, a microprocessor 312 and an answering tone blocker 314. The calling tone detector 310 monitors the communication channel which has been established in order to detect the calling tone. When a calling tone is transmitted from an originating node 40, the calling tone detector 310 detects the calling tone, which causes the base station controller 20 to initiate the switch to a higher data transmission rate. The microprocessor 312 subsequently informs any other base stations 14 or subscriber units 16 through which the communication is to be routed (hereinafter called communicating equipment) to initiate the switch to the higher data transmission rate.

[0040] The microprocessor 312 activates the answering tone blocker 314 which will prevent the answering tone from being transmitted through the system 10. Each piece of

communicating equipment 14, 16, 20 transmits an acknowledgment to the microprocessor 312 of the base station controller 20 when the higher data transmission rate has been achieved. The microprocessor 312 subsequently deactivates the answering tone blocker 314 which permits the answering tone to be forwarded to the originating node 40. The communicating nodes 40, 44 commence data transmission over the communication system 10 at the higher data transmission rate.

[0041] Although the invention has been described in part by making detailed reference to the preferred embodiment, such detail is intended to be instructive rather than restrictive. For example, the functions performed by the base station controller 20 shown in Figure 5 may, in an alternative embodiment, be performed by a base station 14 coupled with either the originating or terminating nodes 40. The functions of a base station 14 may also be combined with the base station controller 20, to form a master base station. Additionally, different data rates and modulation schemes may be employed. It will be appreciated by those skilled in the art that many variations may be made in the structure and mode of operation without departing from the spirit and scope of the invention as disclosed in the teachings herein.
